## 8. Energetics I

Definition: Enthalpy change is the amount of heat energy taken in or given out during any change in a system provided the pressure is constant.

In an exothermic change energy is transferred from the system (chemicals) to the surroundings.
The products have less energy than the reactants

If an enthalpy change occurs then energy is transferred between system and surroundings. The system is the chemicals and the surroundings is everything outside the chemicals.

In an endothermic change, energy is transferred from the surroundings to the system (chemicals). They require an input of heat energy e.g. thermal decomposition of calcium carbonate
The products have more energy than the reactants

In an endothermic reaction the $\Delta \mathrm{H}$ is positive

Common oxidation exothermic processes are the combustion of fuels and the oxidation of carbohydrates such as glucose in respiration

$$
\begin{aligned}
& \mathrm{Mg}(\mathrm{~s})+\mathrm{Cl}_{2}(\mathrm{~g}) \rightarrow \mathrm{MgCl}_{2}(\mathrm{~s}) \\
& 2 \mathrm{Fe}(\mathrm{~s})+1.5 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{Fe}_{2} \mathrm{O}_{3}(\mathrm{~s})
\end{aligned}
$$

The enthalpy of formation of an element $=0 \mathrm{~kJ} \mathrm{~mol}^{-1}$
$\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \rightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{I})$
Incomplete combustion will lead to soot (carbon), carbon monoxide and water. It will be less exothermic than complete combustion.

```
When an enthalpy change is
measured at standard
conditions the symbol \(\rightarrow\) is
used
\(\mathrm{Eg} \Delta \mathrm{H}^{-}\)
```

Enthalpy changes are normally quoted at standard conditions.
Standard conditions are :

- 100 kPa pressure
- $\quad 298 \mathrm{~K}$ (room temperature or $25^{\circ} \mathrm{C}$ )
- $\quad$ Solutions at $1 \mathrm{~mol} \mathrm{dm}^{-3}$
- all substances should have their normal state at 298 K

Definition: Enthalpy change of reaction is the enthalpy change when the number of moles of reactants as specified in the balanced equation react together

## Enthalpy change of neutralisation

The standard enthalpy change of neutralisation is the enthalpy change when solutions of an acid and an alkali react together under standard conditions to produce 1 mole of water.

Enthalpy changes of neutralisation are always exothermic. For reactions involving strong acids and alkalis, the values are similar, with values between -56 and $-58 \mathrm{~kJ} \mathrm{~mol}^{-1}$

## Hess's Law

Hess's law states that total enthalpy change for a reaction is independent of the route by which the chemical change takes place

Hess's law is a version of the first law of thermodynamics, which is that energy is always conserved.

On an energy level diagram the directions of the arrows can show the different routes a reaction can proceed by

In this example one route is arrow 'a'
The second route is shown by arrows H plus arrow 'b'
So $\mathbf{a}=\mathbf{H}+\mathbf{b}$
And rearranged

$$
H=a-b
$$

Often Hess's law cycles are used to measure the enthalpy change for a reaction that cannot be measured directly by experiments. Instead alternative reactions are carried out that can be measured experimentally.

This Hess's law is used to work out the enthalpy change to form a hydrated salt from an anhydrous salt.

This cannot be done experimentally because it is impossible to add the exact amount of water and it is not easy to measure the temperature change of a solid.

Instead both salts are dissolved in excess water to form a solution of copper sulfate. The temperature changes can be measured for these reactions.

This Hess's law is used to work out the enthalpy change for the thermal decomposition of calcium carbonate.

This cannot be done experimentally because it is impossible to add the heat required to decompose the solid and to measure the temperature change of a solid at the same time.

Instead both calcium carbonate and calcium oxide are reacted with hydrochloric acid to form a solution of calcium chloride. The temperature changes can be measured for these reactions.

## Using Hess's law to determine enthalpy changes from enthalpy changes of formation.

Example 1. Calculate the enthalpy change for this reaction
$\mathrm{Al}_{2} \mathrm{O}_{3}+3 \mathrm{Mg} \rightarrow 3 \mathrm{MgO}+2 \mathrm{Al}$
$\Delta \mathrm{H}=\boldsymbol{\Sigma} \Delta_{\mathrm{f}} \mathrm{H}$ products $-\boldsymbol{\Sigma} \Delta_{\mathrm{f}} \mathrm{H}$ reactants
$\Delta \mathrm{H}=3 \times \Delta_{\mathrm{f}} \mathrm{H}(\mathrm{MgO})-\Delta_{\mathrm{f}} \mathrm{H}\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)$
Remember elements have
$\Delta_{\mathrm{f}} \mathrm{H}=0$
$\Delta H=(3 x-601.7)--1675.7$
$=-129.4 \mathrm{~kJ} \mathrm{~mol}^{-1}$
$\Delta_{\mathrm{t}} \mathrm{H}(\mathrm{MgO})=-601.7 \mathrm{~kJ} \mathrm{~mol}^{-1}$
$\Delta_{\mathrm{t}} \mathrm{H}\left(\mathrm{Al}_{2} \mathrm{O}_{3}\right)=-1675.7 \mathrm{~kJ} \mathrm{~mol}^{-1}$

$$
2 \mathrm{Al}(\mathrm{~s})+3 \mathrm{Mg}(\mathrm{~s})+1.5 \mathrm{O}_{2}(\mathrm{~g})
$$

Example 2. Use the following data to calculate the enthalpy of combustion of propene
$\Delta_{\mathrm{f}} \mathrm{H}_{\mathrm{C}} \mathrm{H}_{6}(\mathrm{~g})=+20 \mathrm{~kJ} \mathrm{~mol}^{-1}$
$\Delta_{\mathrm{f}} \mathrm{H} \mathrm{CO}_{2}(\mathrm{~g})=-394 \mathrm{~kJ} \mathrm{~mol}^{-}$
$\Delta_{\mathrm{f}} \mathrm{H}_{\mathrm{H}} \mathrm{O}(\mathrm{g})=-242 \mathrm{~kJ} \mathrm{~mol}^{-1}$
$\mathrm{C}_{3} \mathrm{H}_{6}+4.5 \mathrm{O}_{2} \rightarrow 3 \mathrm{CO}_{2}+3 \mathrm{H}_{2} \mathrm{O}$
$\Delta_{\mathrm{c}} \mathrm{H}=\boldsymbol{\Sigma} \Delta_{\mathrm{f}} \mathrm{H}$ products $-\boldsymbol{\Sigma} \Delta_{\mathrm{f}} \mathrm{H}$ reactants
$\Delta_{\mathrm{c}} \mathrm{H}=\left[3 \times \Delta_{\mathrm{f}} \mathrm{H}\left(\mathrm{CO}_{2}\right)+3 \times \Delta_{\mathrm{f}} \mathrm{H}\left(\mathrm{H}_{2} \mathrm{O}\right)\right]-\Delta_{\mathrm{f}} \mathrm{H}\left(\mathrm{C}_{3} \mathrm{H}_{6}\right)$
$\Delta \mathrm{c} H=[(3 \mathrm{x}-394)+(3 \mathrm{x}-242)]-20$
$=-1928 \mathrm{~kJ} \mathrm{~mol}^{-1}$

Using Hess's law to determine enthalpy changes from enthalpy changes of combustion.

Example 3. Use the following combustion data to calculate the enthalpy of reaction

$$
\mathrm{CO}(\mathrm{~g})+2 \mathrm{H}_{2}(\mathrm{~g}) \rightarrow \mathrm{CH}_{3} \mathrm{OH}(\mathrm{~g})
$$

$\Delta \mathrm{cHCO}(\mathrm{g})=-283 \mathrm{~kJ} \mathrm{~mol}^{-1} \quad \Delta \mathrm{cH} \mathrm{H}_{2}(\mathrm{~g})=-286 \mathrm{~kJ} \mathrm{~mol}^{-1} \quad \Delta \mathrm{cH} \mathrm{CH}_{3} \mathrm{OH}(\mathrm{g})=-671 \mathrm{~kJ} \mathrm{~mol}^{-1}$

$$
\begin{aligned}
& \Delta \mathrm{H} \text { reaction }=\Sigma \Delta \mathrm{cH} \text { reactants }-\boldsymbol{\Sigma} \Delta \mathrm{cH} \text { products } \\
& \Delta \mathrm{H}=\Delta \mathrm{cH}(\mathrm{CO})+2 \times \Delta \mathrm{cH}\left(\mathrm{H}_{2}\right)-\Delta \mathrm{cH}\left(\mathrm{CH}_{3} \mathrm{OH}\right) \\
& \Delta \mathrm{H}=-283+2 \mathrm{x}-286--671 \\
& \quad=-184 \mathrm{~kJ} \mathrm{~mol}^{-1}
\end{aligned}
$$

Example 4. Use the following combustion data to calculate the enthalpy of formation of propene

$$
3 \mathrm{C}(\mathrm{~s})+3 \mathrm{H}_{2}(\mathrm{~g}) \rightarrow \mathrm{C}_{3} \mathrm{H}_{6} \text { (g) }
$$

$\Delta \mathrm{cHC}(\mathrm{s})=-393 \mathrm{~kJ} \mathrm{~mol}^{-1} \quad \Delta \mathrm{cH} \mathrm{H} 2(\mathrm{~g})=-286 \mathrm{~kJ} \mathrm{~mol}^{-1} \quad \Delta \mathrm{cH} \mathrm{C}_{3} \mathrm{H}_{6}(\mathrm{~g})=--2058 \mathrm{~kJ} \mathrm{~mol}^{-1}$

$$
\begin{aligned}
\Delta \mathrm{H} & =\boldsymbol{\Sigma} \Delta_{\mathrm{c}} \mathrm{H} \text { reactants }-\boldsymbol{\Sigma} \Delta_{\mathrm{c}} \mathrm{H} \text { products } \\
\Delta_{\mathrm{f}} \mathrm{H} & =3 \times \Delta_{\mathrm{c}} \mathrm{H}(\mathrm{C})+3 \times \Delta_{\mathrm{c}} \mathrm{H}\left(\mathrm{H}_{2}\right)-\Delta_{\mathrm{c}} \mathrm{H}\left(\mathrm{C}_{3} \mathrm{H}_{6}\right) \\
\Delta_{\mathrm{f}} \mathrm{H} & =3 \mathrm{x}-393+3 \mathrm{x}-286--2058 \\
& =+21 \mathrm{~kJ} \mathrm{~mol}^{-1}
\end{aligned}
$$

## Measuring the enthalpy change for a reaction experimentally

## Calorimetric method

For a reaction in solution we use the following equation energy change $=$ mass of solution $\mathbf{x}$ heat capacity $\mathbf{x}$ temperature change $Q(\mathrm{~J}) \quad=\mathrm{m}(\mathrm{g}) \quad \mathrm{x} \quad \mathrm{c}_{\mathrm{p}}\left(\mathrm{Jg}^{-1} \mathrm{~K}^{-1}\right) \mathrm{x} \quad \Delta \mathrm{T}(\mathrm{K})$

This equation will only give the energy for the actual quantities used. Normally this value is converted into the energy change per mole of one of the reactants. (The enthalpy change of reaction, $\Delta_{r} \mathrm{H}$ )

## Calorimetric method

Practical

One type of experiment is one in which substances are mixed in an insulated container and the temperature rise measured.

This could be a solid dissolving or reacting in a solution or it could be two solutions reacting together

## General method

- washes the equipment (cup and pipettes etc) with the solutions to be used
- dry the cup after washing
- put polystyrene cup in a beaker for insulation and support
- Measure out desired volumes of solutions with volumetric pipettes and transfer to insulated cup
- clamp thermometer into place making sure the thermometer bulb is immersed in solution
- measure the initial temperatures of the solution or both solutions if 2 are used. Do this every minute for 2-3 minutes
- At minute 3 transfer second reagent to cup. If a solid reagent is used then add the solution to the cup first and then add the solid weighed out on a balance.
- If using a solid reagent then use 'before and after' weighing method
- stirs mixture (ensures that all of the solution is at the same temperature)
- Record temperature every minute after addition for several minutes

If the reaction is slow then the exact temperature rise can be difficult to obtain as cooling occurs simultaneously with the reaction

To counteract this we take readings at regular time intervals and extrapolate the temperature curve/line back to the time the reactants were added together.

We also take the temperature of the reactants for a few minutes before they are added together to get a better average temperature. If the two reactants are solutions then the temperature of both solutions need to be measured before addition and an average temperature is used.

## Errors in this method

- energy transfer from surroundings (usually loss)
- approximation in specific heat capacity of solution. The method assumes all solutions have the heat capacity of water.
- neglecting the specific heat capacity of the calorimeter- we ignore any energy absorbed by the apparatus.
- reaction or dissolving may be incomplete or slow.
- density of solution is taken to be the same as water.

Read question carefully. It may be necessary to describe:

- Method
- Drawing of graph with extrapolation
- Description of the calculation

## Calculating the enthalpy change of reaction, $\Delta \mathbf{H}_{\mathrm{r}}$ from experimental data

General method

1. Using $\mathbf{q}=\mathbf{m} \times \mathbf{c}_{\mathbf{p}} \mathbf{x} \Delta \mathbf{T}$ calculate energy change for quantities used
2. Work out the moles of the reactants used

The heat capacity of water is $4.18 \mathrm{~J} \mathrm{~g}^{-1} \mathrm{~K}^{-1}$. In any reaction where the reactants are dissolved in water we assume that the heat capacity is the same as pure water.
3. Divide $q$ by the number of moles of the reactant not in excess to give $\Delta \mathbf{H}$
4. Add a sign and unit (divide by a thousand to convert $\mathrm{Jmol}^{-1}$ to $\mathrm{kJmol}^{-1}$

Also assume that the solutions have the density of water, which is $1 \mathrm{~g} \mathrm{~cm}^{-3}$. $\mathrm{Eg} 25 \mathrm{~cm}^{3}$ will weigh 25 g

Example 5. Calculate the enthalpy change of reaction for the reaction where $25 \mathrm{~cm}^{3}$ of $0.2 \mathrm{~mol} \mathrm{dm}^{-3}$ copper sulfate was reacted with 0.01 mol (excess of zinc). The temperature increased $7^{\circ} \mathrm{C}$.

Step 1: Calculate the energy change for the amount of reactants in the calorimeter.

$$
\begin{aligned}
& \mathrm{Q}=\mathrm{m} \times \mathrm{c}_{\mathrm{p}} \times \Delta \mathrm{T} \\
& \mathrm{Q}=25 \times 4.18 \times 7 \\
& \mathrm{Q}=731.5 \mathrm{~J}
\end{aligned}
$$

Note the mass is the mass of the copper sulfate solution only. Do not include mass of zinc powder.

Step 2 : calculate the number of moles of the reactant not in excess.

$$
\begin{aligned}
\text { moles of } \mathrm{CuSO}_{4} & =\operatorname{conc} \times \mathrm{vol} \\
& =0.2 \times 25 / 1000 \\
& =0.005 \mathrm{~mol}
\end{aligned}
$$

If you are not told what is in excess, then you need to work out the moles of both reactants and work out using the balanced equation which one is in excess.

Step 3 : calculate the enthalpy change per mole which is often called $\Delta \mathrm{H}$ (the enthalpy change of reaction)

$$
\begin{aligned}
& \Delta \mathrm{H}=\mathrm{Q} / \mathrm{no} \text { of moles } \\
& =731.5 / 0.005 \\
& =146300 \mathrm{~J} \mathrm{~mol}^{-1} \\
& =146 \mathrm{~kJ} \mathrm{~mol}^{-1} \text { to } \mathbf{3 ~ s f}
\end{aligned}
$$

Finally add in the sign to represent the energy change: if temp increases the reaction is exothermic and is given a minus sign e.g. $\mathbf{- 1 4 6} \mathbf{~ k J ~ m o l}^{-1}$

Remember in these questions: sign, unit, sig
figs same as data given.

Example 6. $25 \mathrm{~cm}^{3}$ of $2 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{HCl}$ was neutralised by $25 \mathrm{~cm}^{3}$ of $2 \mathrm{~mol} \mathrm{dm}^{-3} \mathrm{NaOH}$. The temperature increased $13.5^{\circ} \mathrm{C}$. Calculate the enthalpy change per mole of HCl ?

Step 1: Calculate the energy change for the amount of reactants in the calorimeter.

$$
\begin{aligned}
& \mathrm{Q}=\mathrm{m} \times \mathrm{c}_{\mathrm{p}} \times \Delta \mathrm{T} \\
& \mathrm{Q}=50 \times 4.18 \times 13.5 \\
& \mathrm{Q}=2821.5 \mathrm{~J}
\end{aligned}
$$

Note the mass equals the mass of acid + the mass of alkali, as they are both solutions.

Step 2 : calculate the number of moles of the HCl .

$$
\begin{aligned}
\text { moles of } \mathrm{HCl} & =\text { conc } \times \mathrm{vol} \\
& =2 \times 25 / 1000 \\
& =0.05 \mathrm{~mol}
\end{aligned}
$$

Step 3 : calculate $\Delta \mathrm{H}$, the enthalpy change per mole which can be called the enthalpy change of neutralisation

```
\DeltaH=Q/ no of moles
    = 2821.5/0.05
    = 56430 J mol
    = -56.4 kJ mol}\mp@subsup{}{}{-1}\mathrm{ to 3 sf
        Exothermic and so is given a minus sign
```

Remember in these questions: sign, unit, sig figs same as data given.

## Measuring enthalpies of combustion using calorimetry

Enthalpies of combustion can be calculated by using calorimetry. Generally the fuel is burnt and the flame is used to heat up water in a metal cup.

Example 7. Calculate the enthalpy change of combustion for the reaction where 0.65 g of propan- 1 -ol was completely combusted and used to heat up 150 g of water from 20.1 to $45.5^{\circ} \mathrm{C}$

Step 1: Calculate the energy change used to heat up the water.

$$
\begin{aligned}
& Q=m \times c_{p} \times \Delta T \\
& Q=150 \times 4.18 \times 25.4 \\
& Q=15925.8 \mathrm{~J}
\end{aligned}
$$

Note the mass is the mass of water in the calorimeter and not the alcohol

Step 2 : calculate the number of moles of alcohol combusted.

$$
\begin{aligned}
\text { moles of propan-1-ol } & =\text { mass } / \mathrm{Mr} \\
& =0.65 / 60 \\
& =0.01083 \mathrm{~mol}
\end{aligned}
$$

Step 3 : calculate the enthalpy change per mole which is called $\Delta_{\mathrm{c}} \mathrm{H}$ (the enthalpy change of combustion)

$$
\begin{aligned}
\Delta \mathrm{H} & =\mathrm{Q} / \mathrm{no} \text { of moles } \\
& =15925.8 / 0.01083 \\
& =1470073 \mathrm{~J} \mathrm{~mol}^{-1} \\
& =1470 \mathbf{~ k J ~ m o l}^{-1} \text { to } \mathbf{3 ~ s f}
\end{aligned}
$$

Finally add in the sign to represent the energy change: if temp increases

Remember in these questions: sign, unit, 3 sig figs. the reaction is exothermic and is given a minus sign eg -1470 $\mathbf{k J ~ m o l}^{-1}$

## Errors in this method

- Energy losses from calorimeter
- Incomplete combustion of fuel
- Incomplete transfer of energy
- Evaporation of fuel after weighing
- Heat capacity of calorimeter not included
- Measurements not carried out under standard conditions as $\mathrm{H}_{2} \mathrm{O}$ is gas, not liquid, in this experiment

## Mean Bond enthalpies

Definition: The mean bond enthalpy is the enthalpy needed to break the covalent bond into gaseous atoms, averaged over different molecules

We use values of mean bond enthalpies because every single bond in a compound has a slightly different bond energy. E.g. In $\mathrm{CH}_{4}$ there are $4 \mathrm{C}-\mathrm{H}$ bonds. Breaking each one will require a different amount of energy. However, we use an average value for the C-H bond for all hydrocarbons.

The value for the bond enthalpy for the C-H bond in methane matches this reaction $1 / 4 \mathrm{CH}_{4(\mathrm{~g})} \rightarrow \mathrm{C}_{(\mathrm{g})}+\mathrm{H}_{(\mathrm{g})}$

Reaction profile for an exothermic reaction

In an exothermic reaction the sum of the bonds in the reactant molecules will be less than the sum of the bonds in the product molecules

In general (if all substances are gases)
$\Delta \boldsymbol{H}=\Sigma$ bond enthalpies broken $-\Sigma$ bond enthalpies made

$\Delta \boldsymbol{H}$ values calculated using this method will be less accuate than using formation or combustion data because the mean bond energies are not exact

Example 8. Using the following mean bond enthalpy data to calculate the enthalpy of combustion of propene

$\Delta \boldsymbol{H}=\Sigma$ bond enthalpies broken $-\Sigma$ bond enthalpies made

$$
\begin{aligned}
= & {[\mathrm{E}(\mathrm{C}=\mathrm{C})+\mathrm{E}(\mathrm{C}-\mathrm{C})+6 \times \mathrm{E}(\mathrm{C}-\mathrm{H})+4.5 \times \mathrm{E}(\mathrm{O}=\mathrm{O})]-[6 \times \mathrm{E}(\mathrm{C}=\mathrm{O})+6 \mathrm{E}(\mathrm{O}-\mathrm{H})] } \\
= & {[612+348+(6 \times 412)+(4.5 \times 496)]-[(6 \times 743)+(6 \times 463)] } \\
& =-1572 \mathrm{kJmol}^{-1}
\end{aligned}
$$

| Bond | Mean enthalpy <br> (kJ mol-1) |
| :--- | :--- |
| C=C | 612 |
| C-C | 348 |
| O=O | 496 |
| O=C | 743 |
| O-H | 463 |
| C-H | 412 |

Example 9. Using the following mean bond enthalpy data to calculate the enthalpy of formation of $\mathrm{NH}_{3}$ $1 / 2 \mathrm{~N}_{2}+1.5 \mathrm{H}_{2} \rightarrow \mathrm{NH}_{3}$ (note the balancing is to agree with the definition of enthalpy of formation (i.e. one mole of product)

$$
E(N \equiv N)=944 \mathrm{~kJ} \mathrm{~mol}^{-1} \quad E(\mathrm{H}-\mathrm{H})=436 \mathrm{~kJ} \mathrm{~mol}^{-1} \quad E(N-H)=388 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

$\Delta H=\Sigma$ bond enthalpies broken $-\Sigma$ bond enthalpies made

$$
=[0.5 \times \mathrm{E}(\mathrm{~N} \equiv \mathrm{~N})+1.5 \times \mathrm{E}(\mathrm{H}-\mathrm{H})] \quad-[3 \times \mathrm{E}(\mathrm{~N}-\mathrm{H})]
$$

$$
=[(0.5 \times 944)+(1.5 \times 436)]-[3 \times 388)]
$$

$$
=-38 \mathrm{kJmol}^{-1}
$$

## A more complicated example that may occur

| Working out $\Delta_{\mathrm{f}} \boldsymbol{H}$ of a compound using bond energies and other data |
| :--- | :--- | :--- |

## Example 10

Calculate ${ }_{\mathrm{f}} \mathrm{H}$ for propane, $\mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})$, given the following data.
$\mathrm{C}(\mathrm{s}) \rightarrow \mathrm{C}(\mathrm{g}) \quad \mathrm{H}=715 \mathrm{~kJ} \mathrm{~mol}^{-1}$
$3 \mathrm{C}(\mathrm{s})+4 \mathrm{H}_{2}(\mathrm{~g}) \rightarrow \mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})$,

| Bond | $\mathrm{C}-\mathrm{C}$ | $\mathrm{C}-\mathrm{H}$ | $\mathrm{H}-\mathrm{H}$ |
| :---: | :---: | :---: | :--- |
| $\mathrm{kJ} \mathrm{mol}^{-1}$ | 348 | 412 | 436 |

$\Delta_{\mathrm{f}} \boldsymbol{H}=$| $\boldsymbol{\Sigma} \Delta \mathrm{H}$ to turn elements |
| :--- |
| into gaseous atoms |$-$| $\boldsymbol{\Sigma} \Delta \mathrm{H}$ to turn compound |
| :--- |
| into gaseous atoms |

$$
\begin{aligned}
\Delta_{\mathrm{f}} \mathrm{H}= & \left(3 \times \Delta \mathrm{H}_{\mathrm{at}}[\mathrm{C}]+4 \times \mathrm{E}[\mathrm{H}-\mathrm{H}]\right)-(2 \times \mathrm{E}[\mathrm{C}-\mathrm{C}]+8 \times \mathrm{E}[\mathrm{C}-\mathrm{H}]) \\
= & (3 \times 715+4 \times 436)-(2 \times 348+8 \times 412) \\
& =-103 \mathrm{~kJ} \mathrm{~mol}^{-1}
\end{aligned}
$$

## Enthalpies of combustion in a homologous series

When comparing the heats of combustion for successive members of a homologous series such as alkanes or alcohols there is a constant rise in the size of the heats of combustion as the number of carbon atoms increases

ethanol

Propan-1-ol
$\mathbf{1 C - C}, 5 \mathbf{C - H} 1 \mathrm{C}-\mathrm{O} 1 \mathrm{O}-\mathrm{H}$ and $3 \mathbf{O = O}$ bonds are broken
$4 \mathrm{C}=\mathbf{O}$ and $6 \mathrm{O}-\mathrm{H}$ bonds are made

$$
\mathrm{H}_{\mathrm{c}}=-1365 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

2C-C, 7C-H 1C-O 1O-H and $4.5 \mathrm{O}=0$ bonds are broken
$6 \mathrm{C}=\mathbf{0}$ and $8 \mathrm{O}-\mathrm{H}$ bonds are made
$\mathrm{H}_{\mathrm{c}}=-2016 \mathrm{~kJ} \mathrm{~mol}^{-1}$

Butan-1-ol
$3 \mathrm{C}-\mathrm{C}, 9 \mathrm{C}-\mathrm{H} 1 \mathrm{C}-\mathrm{O} 1 \mathrm{O}-\mathrm{H}$ and $6 \mathrm{O}=\mathbf{O}$ bonds are broken
$8 \mathrm{C}=\mathbf{O}$ and $10 \mathrm{O}-\mathrm{H}$ bonds are made

$$
\mathrm{H}_{\mathrm{c}}=-2677 \mathrm{~kJ} \mathrm{~mol}^{-1}
$$

As one goes up the homologous series there is a constant amount and type of extra bonds being broken and made e.g. 1C-C, 2C-H and $1.5 \mathrm{O}=\mathrm{O}$ extra bonds broken and $2 \mathrm{C}=\mathrm{O}$ and $2 \mathrm{O}-\mathrm{H}$ extra bonds made, so the enthalpy of combustion increases by a constant amount

If the results are worked out experimentally using a calorimeter the experimental results will be much lower than the calculated ones because there will be significant heat loss. There will also be incomplete combustion which will lead to less energy being released.

Remember that calculated values of enthalpy of combustions will be more accurate if calculated from enthalpy of formation data than if calculated from average bond enthalpies. This is because average bond enthalpy values are averaged values of the bond enthalpies from various compounds.
